A dissociation of performance and awareness during binocular rivalry

Authors: Baker & Cass (York)

Journal: Psychological Science, 24, 2563-2568 (2013)

DOI: 10.1177

ABSTRACT

Conflicting stimuli to each eye -> binocular rivalry alternations. Objective measurement with monocular probe-detection shows reduced sensitivity during suppression, but is it true blindsight or probe-induced switch? Measured judgment accuracy and confidence across multiple probe contrasts. Evidence for high accuracy with reduced awareness during suppression not due to probe-induced switches. Blindsight-like behavior in normal observers. Quantifies performance (d') vs awareness (confidence) dissociation.

What was actually measured (numbers):

Multiple probe contrast levels, d' and confidence ratings, dissociation quantified

Devices / Protocol:

Stereoscope, psychophysics probe detection, confidence scales

Replication across teams / Independence:

Classic paradigm replicated across York lab, cited in Blake et al. Phil Trans B 2014
